

Astronomy from 4 Perspectives: the Dark Universe

prepared by: Florence participants and Björn Malte Schäfer

Exercise: Supernova cosmology and dark energy

1. Light-propagation in FLRW-spacetimes

Photons travel along null geodesics, $ds^2 = 0$, in any spacetime.

- (a) Please show that by introducing *conformal time* τ in a suitable definition, one recovers Minkowski light propagation $c\tau = \pm\chi$ in comoving distance χ and conformal time τ for FLRW-spacetimes,

$$ds^2 = c^2 d\tau^2 - a^2(t) d\chi^2, \quad (\text{I})$$

which we have assumed to be spatially flat for simplicity.

- (b) What's the relationship between conformal time τ and cosmic time t ? What would the watch of a cosmological observer display?
- (c) Please compute the conformal age of the Universe given a Hubble function $H(a)$,

$$H(a) = H_0 a^{-3(1+w)/2} \quad (\text{II})$$

which is filled up to the critical density with a fluid with a fixed equation of state w .

- (d) In applying $ds^2 = 0$ to the FLRW-metric we have assumed a radial geodesic - is this a restriction?
- (e) Please draw a diagram of a photon propagating from a distant galaxy to us in conformal coordinates for a cosmology of your choice, with markings on the light-cone corresponding to equidistant Δa .

2. Light-propagation in perturbed metrics

The weakly perturbed ($|\Phi| \ll c^2$) Minkowski metric is given by

$$ds^2 = \left(1 + 2\frac{\Phi}{c^2}\right) c^2 dt^2 - \left(1 - 2\frac{\Phi}{c^2}\right) dx_i dx^i \quad (\text{III})$$

with the Newtonian potential Φ . Please compute the effective speed of propagation $c' = d|x|/dt$ for a photon following a null geodesic $ds^2 = 0$. Please Taylor-expand the expression in the weak-field limit $|\Phi| \ll c^2$: Can you assign an effective index of refraction to a region of space with a nonzero potential?

3. Classical potentials including a cosmological constant

The field equation of classical gravity including a cosmological dark energy density λ is given by

$$\Delta\Phi = 4\pi G(\rho + \lambda) \quad (\text{IV})$$

- (a) Solve the field equation for 3 dimensions outside a spherically symmetric and static matter distribution ρ . The expression for the Laplace-operator in spherical coordinates for 3 dimensions is: $\Delta\Phi = r^{-2}\partial_r(r^2\partial_r\Phi)$. Also, please set as the total baryon mass M

$$M = 4\pi \int_0^r dr' (r')^2 \rho(r') \quad (\text{V})$$

- (b) Please show that both source terms individually give rise to power-law solutions for $\Phi(r)$.
- (c) Is there a distance where the baryon part from the ρ -terms is equal to dark energy part the λ -term?
- (d) Assuming a typical galaxy is formed by 100 billion stars like the Sun each with a mass of 10^{30} kg, and a dark energy density of 10^{-27} kg / m³, find at which distance from a galaxy the dark energy dominates. How does it compare with the typical size of a Galaxy (~ 10000 pc)?

4. *Physics close to the horizon*

Why is it necessary to observe supernovae at the Hubble distance c/H_0 to see the dimming in accelerated cosmologies? Please start at considering the curvature scale of the Universe: A convenient measure for the curvature might be the Ricci-scalar $R = 6H^2(1 - q)$ for flat FLRW-models.

- (a) Can you define a distance scale d or a time scale from R ?
- (b) What happens on scales $\ll d$, what on scales $\gg d$?

5. *Measuring cosmic acceleration*

The luminosity distance $d_{\text{lum}}(z)$ in a spatially flat FLRW-universe is given by

$$d_{\text{lum}}(z) = (1 + z) \int_0^z dz' \frac{1}{H(z')} \quad (\text{VI})$$

with the Hubble function $H(z)$. Let's assume that the Universe is filled with a cosmological fluid up to the critical density with a fluid with equation of state w , such that the Hubble function is

$$H(z) = H_0(1 + z)^{\frac{3(1+w)}{2}}. \quad (\text{VII})$$

- (a) For this type of cosmology you will obtain acceleration if $w < -1/3$ and deceleration for $w > -1/3$: Please show this by computing the deceleration parameter $q = -\ddot{a}a/\dot{a}^2$ from the Hubble-function $H = \dot{a}/a$, with the relation $a = 1/(1 + z)$.
- (b) Please show that in accelerated universes supernovae appear systematically dimmer, because d_{lum} is always larger than in a non-accelerating universe.
- (c) Is it true that d_{lum} is systematically smaller in a decelerating universe?
- (d) Would the expression for d_{lum} still be valid if the universe was contracting instead of expanding? What correction would you need to apply?
